logbin-package	<i>Relative Risk Regression Using the Log-Binomial Model</i>
----------------	--

Description

Methods for fitting log-link GLMs and GAMs to binomial data, including EM-type algorithms with more stable convergence properties than standard methods.

Details

Package: logbin
 Type: Package
 Version: 2.0.5
 License: GPL (>= 2)

This package provides methods to fit generalised linear models (GLMs) and generalised additive models (GAMs) with log link functions to binomial data, which can be used to estimate adjusted relative risks. It has two primary functions: `logbin` and `logbin.smooth`, together with various supporting functions.

Standard GLM routines such as base R's `glm` typically use a modified Fisher scoring algorithm, but this can experience numerical problems and fail to converge to the maximum likelihood estimate (MLE). The `glm2` package improves on this but can still have difficulties, particularly when the MLE is on or near the boundary of the parameter space (Marschner, 2015).

Alternative methods for finding the MLE are provided in this package. For both GLMs and GAMs, two approaches based on the EM algorithm can be used: a combinatorial EM (CEM) algorithm (Marschner, 2014) or an expanded EM algorithm. These accomodate the parameter constraints and are more stable than iteratively reweighted least squares.

In a CEM algorithm, a collection of restricted parameter spaces is defined which covers the full parameter space, and an EM algorithm is applied within each restricted parameter space in order to find a collection of restricted maxima of the log-likelihood function, from which can be obtained the global maximum over the full parameter space. The methodology implemented for this algorithm is presented in Marschner and Gillett (2012) and Donoghoe and Marschner (2015).

In the expanded EM approach, additional parameters are added to the model, and an EM algorithm finds the MLE of this overparameterised model by imposing constraints on each individual parameter. This requires a single application of the EM algorithm.

In each case, the EM algorithm may be accelerated by using the capabilities of the `turboEM` package.

For GLMs, an adaptive barrier approach, which uses a constrained optimisation algorithm, is also provided.

anova.logbin	<i>Analysis of Deviance for logbin Fits</i>
--------------	---

Description

Compute an analysis of deviance table for more than one GLM fitted using [logbin](#).

Usage

```
## S3 method for class 'logbin'
anova(object, ..., test = NULL)
```

Arguments

object, ...	objects of class "logbin", typically the result of a call to logbin , or a list of objects for the "logbinlist" method.
test	a character string, (partially) matching one of "Chisq", "LRT", "Rao", "F" or "Cp". See stat.anova .

Details

Unlike `anova.glm`, specifying a single object is not allowed.

The table has a row for the residual degrees of freedom and deviance for each model. For all but the first model, the change in degrees of freedom and deviance is also given. (This only makes statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

Models where the MLE lies on the boundary of the parameter space will be automatically removed from the list (with a warning), because asymptotic results do not apply to such models.

The table will optionally contain test statistics (and p-values) comparing the reduction in deviance for the row to the residuals. Mallows' C_p statistic is the residual deviance plus twice the estimate of σ^2 times the residual degrees of freedom, which is closely related to AIC. You can also choose "LRT" and "Rao" for likelihood ratio tests and Rao's efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution).

Value

An object of class "anova" inheriting from class "data.frame".

B.Iso

Defining Smooths in logbin.smooth Formulae

Description

Function used in the definition of smooth terms within `logbin.smooth` model formulae. The function does not evaluate a smooth — it exists purely to help set up a model using smooths.

Usage

```
B(..., knots = NULL, knot.range = 0:5)
```

```
Iso(...)
```

Arguments

...	variable that this smooth is a function of. Note that unlike gam , smooths that are functions of more than one variable are not supported.
knots	<i>unique</i> positions of <i>interior</i> knots of a B-spline basis. Boundary knots are created automatically.
knot.range	if knots is not specified, a vector containing a series of non-negative integers denoting the number of <i>interior</i> knots for which the model will be fit. These are placed at evenly-spaced quantiles of the observed covariate values. At least one of knots or knot.range must be non-missing.

Details

The function does not evaluate the variable arguments; the output from this function is used when producing the model matrix, at which point the actual basis functions are constructed.

B is used to specify an order-3 B-spline basis (which can be restricted to be monotonically non-decreasing via the *mono* argument in [logbin.smooth](#)). If `length(knot.range) > 1`, models with each of the specified number of interior knots will be fit, and the model with the best (smallest) `aic.c` will be returned.

Iso is used to specify an isotonic basis, designed such that the resulting function has non-negative increments at each observed covariate value. When Iso is used, the resulting function will always be monotonically non-decreasing, regardless of the value of *mono*.

Value

An object of class "B.smooth" (for B) or "Iso.smooth" (for Iso), which is a list with the following elements:

term	name of the term provided in the ... argument.
termlabel	label for the term in the model; e.g. for term "x" it will be "B(x)" or "Iso(x)".
knots	vector of interior knots (if specified). NA for Iso.
knot.range	vector of number of interior knots. NA for Iso.

`confint.logbin`*Confidence Intervals for logbin Model Parameters*

Description

Computes confidence intervals for one or more parameters in a fitted `logbin` model.

Usage

```
## S3 method for class 'logbin'  
confint(object, parm, level = 0.95, ...)
```

Arguments

<code>object</code>	a fitted model object, resulting from a call to <code>logbin</code> .
<code>parm</code>	a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
<code>level</code>	the confidence level required.
<code>...</code>	additional argument(s) passed to <code>confint.default</code> .

Details

Calculates confidence intervals for model parameters assuming asymptotic normality and using the result from `vcov.logbin(object)`. As such, if the MLE is on the boundary of the parameter space, (as per `object$boundary`) the normality assumption is invalid and NA is returned.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as $(1-\text{level})/2$ and $1-(1-\text{level})/2$ in % (by default 2.5% and 97.5%).

```

contr.isotonic.rev *Contrast Matrix for Reversed Isotonic Covariate*

Description

Return something similar to a contrast matrix for a categorical covariate that we wish to be monotonically non-decreasing in a specified order.

Usage

```
contr.isotonic.rev(n, perm, contrasts = TRUE, sparse = FALSE)
```

Arguments

n	a vector of levels for a factor, or the number of levels.
perm	a permutation of the levels of n (or of the numbers 1:n), which define the order in which the coefficients must be monotonically non-decreasing.
contrasts	a logical indicating whether contrasts should be computed.
sparse	included for compatibility reasons. Has no effect.

Details

This function is used in creating the design matrix for categorical covariates with a specified order under a particular parameterisation. This is required if a categorical covariate is defined as monotonic.

In the order specified by perm, the coefficient associated with each level is the sum of increments between the following levels. That is, if there are a total of k levels, the first level is defined as $d_2 + d_3 + d_4 + \dots + d_k$, the second as $d_3 + d_4 + \dots + d_k$, the third as $d_4 + \dots + d_k$, and so on. In fitting the model, these increments are constrained to be non-positive.

Note that these are not ‘contrasts’ as defined in the theory for linear models, rather this is used to define the contrasts attribute of each variable so that `model.matrix` produces the desired design matrix.

Value

A matrix with n rows and k columns, with $k = n - 1$ if contrasts is TRUE and $k = n$ if contrasts is FALSE.

Author(s)

Mark W. Donoghoe <markdonoghoe@gmail.com>

See Also

[model.matrix](#), which uses `contr.isotonic.rev` to create the design matrix.
[contr.treatment](#), [contrasts](#) for their usual use in regression models.

Examples

```

contr.isotonic.rev(4,1:4)
contr.isotonic.rev(4,c(1,3,2,4))

# Show how contr.isotonic.rev applies within model.matrix
x <- factor(round(runif(20,0,2)))
mf <- model.frame(~x)
contrasts(x) <- contr.isotonic.rev(levels(x), levels(x))
model.matrix(mf)

```

```
interpret.logbin.smooth
```

Interpret a logbin.smooth Formula

Description

This is an internal function of package `logbin`. It is a service routine for `logbin.smooth` which interprets the smooth parts of the model formula and returns modified formulas to be used in the fitting functions.

Not normally called directly.

Usage

```
interpret.logbin.smooth(formula)
```

Arguments

formula	A formula as supplied to <code>logbin.smooth</code> , which includes at least one <code>B</code> or <code>Iso</code> term.
---------	--

Value

A list with components:

full.formula	a <code>formula</code> object which is the same as the formula supplied, but with additional arguments removed from the smooth terms. E.g. <code>B(x, knot.range = 0:2)</code> would appear as <code>B(x)</code> in this formula.
fake.formula	a <code>formula</code> object which is the same as the formula supplied, but with smooth terms replaced by their covariates alone. E.g. <code>B(x, knot.range = 0:2)</code> would appear as <code>x</code> in this formula. Used to construct the model matrix.
smooth.spec	a named list containing the results of evaluating the smooth terms. See <code>B</code> and <code>Iso</code> for details.
smooth.ind	a vector containing the indices of the smooth components in the formula.
terms	the result of running <code>terms.formula(formula, specials = c("B", "Iso"))</code> .

Author(s)

Mark W. Donoghoe <markdonoghoe@gmail.com>

Examples

```
# Specify a smooth model with knot.range
res <- interpret.logbin.smooth(y ~ B(x, knot.range = 0:2) + x2)
# The knot.range is removed from the full.formula...
print(res$full.formula)
# ...but is stored in the $smooth.spec component of the result:
print(res$smooth.spec$x$knot.range)
```

logbin

Log-Binomial Regression

Description

logbin fits relative risk (log-link) binomial regression models.

Usage

```
logbin(formula, mono = NULL, data, subset, na.action, start = NULL,
       offset, control = list(...), model = TRUE,
       method = c("cem", "em", "glm", "glm2", "ab"),
       accelerate = c("em", "squarem", "pem", "qn"),
       control.method = list(), warn = TRUE, ...)
```

Arguments

formula	an object of class " formula " (or one that can be coerced into that class): a symbolic description of the model to be fitted. The details of model specification are given under "Details". Note that the model must contain an intercept, and 2nd-order terms (such as interactions) or above are currently not supported by the "cem" and "em" methods — see "Note".
mono	a vector indicating which terms in formula should be restricted to have a monotonically non-decreasing relationship with the outcome. May be specified as names or indices of the terms. method = "glm" and "glm2" cannot impose monotonicity constraints, and they are not currently supported for method = "ab".
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment (formula), typically the environment from which logbin is called.

subset	an optional vector specifying a subset of observations to be used in the fitting process.
na.action	a function which indicates what should happen when the data contain NAs. The default is set to be the <code>na.action</code> setting of <code>options</code> , and is <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> . Another possible value is <code>NULL</code> , no action. Value <code>na.exclude</code> can be useful.
start	starting values for the parameters in the linear predictor.
offset	this can be used to specify an <i>a priori</i> known component to be included in the linear predictor during fitting. This should be <code>NULL</code> or a <i>non-positive</i> numeric vector of length equal to the number of cases. One or more <code>offset</code> terms can be included in the formula instead or as well, and if more than one is specified their sum is used. See <code>model.offset</code> .
control	a list of parameters for controlling the fitting process, passed to <code>logbin.control</code> . With <code>method = "cem"</code> , <code>epsilon</code> should be smaller than <code>bound.tol</code> .
model	a logical value indicating whether the <i>model frame</i> should be included as a component of the returned value.
method	a character string that determines which algorithm to use to find the MLE. The main purpose of <code>logbin</code> is the implementation of stable EM-type algorithms: <code>"cem"</code> for the combinatorial EM algorithm, which cycles through a sequence of constrained parameter spaces, or <code>"em"</code> for a single EM algorithm based on an overparameterised model. <code>"ab"</code> implements an adaptive barrier method, using the <code>constrOptim</code> function. <code>"glm"</code> or <code>"glm2"</code> may be used to compare the results from the usual IWLS algorithms on the same model.
accelerate	for the <code>"cem"</code> and <code>"em"</code> methods, a character string that determines the acceleration algorithm to be used, (partially) matching one of <code>"em"</code> (no acceleration — the default), <code>"squarem"</code> , <code>"pem"</code> or <code>"qn"</code> . See <code>turboem</code> for further details. Note that <code>"decme"</code> is not permitted.
control.method	a list of control parameters for the fitting algorithm. This is passed to the <code>control.method</code> argument of <code>turboem</code> if <code>method = "cem"</code> or <code>"em"</code> . If <code>method = "ab"</code> , this is passed to the <code>control</code> argument of <code>constrOptim</code> (and hence to <code>optim</code> — see this documentation for full details). Note that the <code>trace</code> and <code>maxit</code> elements are ignored and the equivalent items from the supplied <code>logbin.control</code> argument are used instead. May also contain element <code>method</code> (default <code>"BFGS"</code>), which is passed to the <code>method</code> argument of <code>constrOptim</code> . If any items are not specified, the defaults are used.
warn	a logical indicating whether or not warnings should be provided for non-convergence or boundary values.
...	arguments to be used to form the default <code>control</code> argument if it is not supplied directly.

Details

`logbin` fits a generalised linear model (GLM) with a binomial error distribution and log link function. Predictors are assumed to be continuous, unless they are of class `factor`, or are character or

logical (in which case they are converted to factors). Specifying a predictor as monotonic using the `mono` argument means that for continuous terms, the associated coefficient will be restricted to be non-negative, and for categorical terms, the coefficients will be non-decreasing in the order of the factor `levels`. This allows semi-parametric monotonic regression functions, in the form of unsmoothed step-functions. For smooth regression functions see `logbin.smooth`.

As well as allowing monotonicity constraints, the function is useful when a standard GLM routine, such as `glm`, fails to converge with a log-link binomial model. For convenience in comparing convergence on the same model, `logbin` can be used as a wrapper function to `glm` and `glm2` through the `method` argument.

If `glm` does achieve successful convergence, and `logbin` converges to an interior point, then the two results will be identical. However, as illustrated in one of the examples below, `glm` may still experience convergence problems even when `logbin` converges to an interior point. Note that if `logbin` converges to a boundary point, then it may differ slightly from `glm` even if `glm` successfully converges, because of differences in the definition of the parameter space. `logbin` produces valid fitted values for covariate values within the Cartesian product of the observed range of covariate values, whereas `glm` produces valid fitted values just for the observed covariate combinations (assuming it successfully converges). This issue is only relevant when `logbin` converges to a boundary point. The adaptive barrier approach defines the parameter space in the same way as `glm`, so the same comments apply when comparing its results to those from `method = "cem"` or `"em"`.

The main computational method is an EM-type algorithm which accommodates the parameter constraints in the model and is more stable than iteratively reweighted least squares. This is done in one of two ways, depending on the choice of the `method` argument.

`method = "cem"` implements a CEM algorithm (Marschner, 2014), in which a collection of restricted parameter spaces is defined that covers the full parameter space, and an EM algorithm is applied within each restricted parameter space in order to find a collection of restricted maxima of the log-likelihood function, from which can be obtained the global maximum over the full parameter space. See Marschner and Gillett (2012) for further details.

`method = "em"` implements a single EM algorithm on an overparameterised model, and the MLE of this model is transformed back to the original parameter space.

Acceleration of the EM algorithm in either case can be achieved through the methods of the `turboem` package, specified through the `accelerate` argument. However, note that these methods do not have the guaranteed convergence of the standard EM algorithm, particularly when the MLE is on the boundary of its (possibly constrained) parameter space.

Alternatively, an adaptive barrier method can be used by specifying `method = "ab"`, which maximises the likelihood subject to constraints on the fitted values.

Value

`logbin` returns an object of class `"logbin"`, which inherits from classes `"glm"` and `"lm"`. The function `summary.logbin` can be used to obtain or print a summary of the results.

The generic accessor functions `coefficients`, `fitted.values` and `residuals` can be used to extract various useful features of the value returned by `logbin`. Note that `effects` will not work.

An object of class `"logbin"` is a list containing the same components as an object of class `"glm"` (see the "Value" section of `glm`). It also includes:

`loglik` the maximised log-likelihood.

<code>aic.c</code>	a small-sample corrected version of Akaike's <i>An Information Criterion</i> (Hurvich, Simonoff and Tsai, 1998). This is used by <code>logbin.smooth</code> to choose the optimal number of knots for smooth terms.
<code>xminmax</code>	the minimum and maximum observed values for each of the continuous covariates, to help define the covariate space of the model.
As well as:	
<code>np.coefficients</code>	estimated coefficients associated with the non-positive parameterisation corresponding to the MLE.
<code>nn.x</code>	non-negative model matrix associated with <code>np.coefficients</code> .
<code>coefhist</code>	(if <code>control\$coeftrace = TRUE</code>), a matrix or list of matrices containing the coefficient estimates after each EM iteration.

Note

Due to the way in which the covariate space is defined in the CEM algorithm, models that include terms that are functionally dependent on one another — such as interactions and polynomials — may give unexpected results. Categorical covariates should always be entered directly as factors rather than dummy variables. 2-way interactions between factors can be included by calculating a new factor term that has levels corresponding to all possible combinations of the factor levels (see the Example). Non-linear relationships can be included by using `logbin.smooth`.

```

logbin.control

Auxiliary for Controlling logbin Fitting

Description

Auxiliary function for [logbin](#) fitting. Typically only used internally by [nplbin](#), but may be used to construct a control argument to that function.

Usage

```
logbin.control(bound.tol = 1e-06, epsilon = 1e-08, maxit = 10000, trace = 0,
              coeftrace = FALSE)
```

Arguments

bound.tol	positive tolerance specifying the interior of the parameter space. If the fitted model is more than bound.tol away from the boundary of the parameter space then it is assumed to be in the interior. This can allow the computational method to terminate early if an interior maximum is found. No early termination is attempted if bound.tol = Inf.
epsilon	positive convergence tolerance ϵ ; the estimates are considered to have converged when $\sqrt{\sum(\theta_{old} - \theta_{new})^2} / \sqrt{\sum \theta_{old}^2} < \epsilon$, where θ is the vector of parameter estimates. This should be smaller than bound.tol.
maxit	integer giving the maximum number of iterations (for a given parameterisation in the case of the CEM algorithm).
trace	number indicating level of output that should be produced. ≥ 1 gives output for each parameterisation, ≥ 2 gives output at each iteration.
coeftrace	logical indicating whether the coefficient history should be included as a component of the returned value (for method = "em" and method = "cem").

Details

This is used similarly to [glm.control](#). The control argument of [logbin](#) is by default passed to the control argument of [nplbin](#).

When trace is greater than zero, calls to [cat](#) produce the output. Hence, [options\(digits = *\)](#) can be used to increase the precision.

Value

A list with components named as the arguments.

Author(s)

Mark W. Donoghoe <markdonoghoe@gmail.com>

[nplbin](#), the function used to fit [logbin](#) models.

Examples

```
## Variation on example(glm.control) :

evts <- c(18,17,15,20,10,20,25,13,12)
obs <- rep(30,9)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
oo <- options(digits = 12)
logbin.D93X <- logbin(cbind(evts,obs-evts) ~ outcome + treatment, trace = 2, epsilon = 1e-2)
options(oo)
coef(logbin.D93X)
```

logbin.smooth

Smooth Log-Binomial Regression

Description

logbin.smooth fits log-link binomial regression models using a stable CEM algorithm. It provides additional flexibility over [logbin](#) by allowing for smooth semi-parametric terms.

Usage

```
logbin.smooth(formula, mono = NULL, data, subset, na.action, offset,
              control = list(...), model = TRUE, model.logbin = FALSE,
              method = c("cem", "em"), accelerate = c("em", "squarem", "pem", "qn"),
              control.accelerate = list(), ...)
```

Arguments

formula	an object of class " formula " (or one that can be coerced into that class): a symbolic description of the model to be fitted. The details of model specification are given under "Details". The model must contain an intercept and at least one semi-parametric term, included by using the B or Iso functions. Note that 2nd-order terms (such as interactions) or above are not currently supported (see logbin).
mono	a vector indicating which terms in formula should be restricted to have a monotonically non-decreasing relationship with the outcome. May be specified as names or indices of the terms. Iso() terms are always monotonic.
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment (formula), typically the environment from which logbin.smooth is called.
subset	an optional vector specifying a subset of observations to be used in the fitting process.

na.action	a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of <code>options</code> , and is <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> . Another possible value is <code>NULL</code> , no action. Value <code>na.exclude</code> can be useful.
offset	this can be used to specify an <i>a priori</i> known component to be included in the linear predictor during fitting. This should be <code>NULL</code> or a <i>non-positive</i> numeric vector of length equal to the number of cases. One or more <code>offset</code> terms can be included in the formula instead or as well, and if more than one is specified their sum is used. See <code>model.offset</code> .
control	a list of parameters for controlling the fitting process, passed to <code>logbin.control</code> .
model	a logical value indicating whether the <i>model frame</i> should be included as a component of the returned value.
model.logbin	a logical value indicating whether the fitted logbin object should be included as a component of the returned value.
method	a character string that determines which EM-type algorithm to use to find the MLE: <code>"cem"</code> for the combinatorial EM algorithm, which cycles through a sequence of constrained parameter spaces, or <code>"em"</code> for a single EM algorithm based on an overparameterised model. Unlike <code>logbin</code> , methods <code>"glm"</code> and <code>"ab"</code> are not available because they do not support the necessary monotonicity constraints.
accelerate	a character string that determines the acceleration algorithm to be used, (partially) matching one of <code>"em"</code> (no acceleration – the default), <code>"squarem"</code> , <code>"pem"</code> or <code>"qn"</code> . See <code>turboem</code> for further details. Note that <code>"decme"</code> is not permitted.
control.accelerate	a list of control parameters for the acceleration algorithm. See <code>turboem</code> for details of the parameters that apply to each algorithm. If not specified, the defaults are used.
...	arguments to be used to form the default control argument if it is not supplied directly.

Details

`logbin.smooth` performs the same fitting process as `logbin`, providing a stable maximum likelihood estimation procedure for log-link binomial GLMs, with the added flexibility of allowing semi-parametric **B** and **Iso** terms (note that `logbin.smooth` will stop with an error if no semi-parametric terms are specified in the right-hand side of the formula; `logbin` should be used instead).

The method partitions the parameter space associated with the semi-parametric part of the model into a sequence of constrained parameter spaces, and defines a fully parametric logbin model for each. The model with the highest log-likelihood is the MLE for the semi-parametric model (see Donoghoe and Marschner, 2015).

Value

An object of class `"logbin.smooth"`, which contains the same objects as class `"logbin"` (the same as `"glm"`), as well as:

model.logbin	if model.logbin is TRUE; the logbin object for the fully parametric model corresponding to the fitted model.
xminmax.smooth	the minimum and maximum observed values for each of the smooth terms in the model, to help define the covariate space.
full.formula	the component from <code>interpret.logbin.smooth(formula)</code> that contains the formula term with any additional arguments to the <code>B</code> function removed.
knots	a named list containing the knot vectors for each of the smooth terms in the model.

nplbin *Non-Positive Log-Binomial Regression*

Description

Finds the maximum likelihood estimate of a log-link binomial GLM using an EM algorithm, where each of the coefficients in the linear predictor is restricted to be non-positive.

Usage

```
nplbin(y, x, offset, start, Amat = diag(ncol(x)), control = logbin.control(),
       accelerate = c("em", "squarem", "pem", "qn"),
       control.accelerate = list(list()))
```

Arguments

y	binomial response. May be a single column of 0/1 or two columns, giving the number of successes and failures.
x	non-negative covariate matrix.
offset	non-positive additive offset vector. The default is a vector of zeros.
start	starting values for the parameter estimates. All elements must be less than or equal to <code>-control\$bound.tol</code> .
Amat	matrix that parameter estimates are left-multiplied by before testing for convergence (e.g. to check reduced version of expanded parameter vector).
control	a <code>logbin.control</code> object, which controls the fitting process.
accelerate	a character string that determines the acceleration algorithm to be used, (partially) matching one of "em" (no acceleration – the default), "squarem", "pem" or "qn". See turboem for further details. Note that "decme" is not permitted.
control.accelerate	a list of control parameters for the acceleration algorithm. See turboem for details of the parameters that apply to each algorithm. If not specified, the defaults are used.

Details

This is a workhorse function for `logbin`, and runs the EM algorithm to find the constrained non-positive MLE associated with a log-link binomial GLM. See Marschner and Gillett (2012) for full details.

Value

A list containing the following components

coefficients	the constrained non-positive maximum likelihood estimate of the parameters.
residuals	the residuals at the MLE, that is <code>y - fitted.values</code>

fitted.values	the fitted mean values.
rank	the number of parameters in the model (named "rank" for compatibility — we assume that models have full rank)
family	included for compatibility — will always be <code>binomial(log)</code> .
linear.predictors	the linear fit on link scale.
deviance	up to a constant, minus twice the maximised log-likelihood.
aic	a version of Akaike's <i>An Information Criterion</i> , minus twice the maximised log-likelihood plus twice the number of parameters.
aic.c	a small-sample corrected version of Akaike's <i>An Information Criterion</i> (Hurvich, Simonoff and Tsai, 1998).
null.deviance	the deviance for the null model, comparable with deviance. The null model will include the offset and an intercept.
iter	the number of iterations of the EM algorithm used.
weights	included for compatibility — a vector of ones.
prior.weights	the number of trials associated with each binomial response.
df.residual	the residual degrees of freedom.
df.null	the residual degrees of freedom for the null model.
y	the y vector used.
converged	logical. Did the EM algorithm converge?
boundary	logical. Is the MLE on the boundary of the parameter space — i.e. are any of the coefficients <code>< control\$bound.tol</code> ?
loglik	the maximised log-likelihood.
nn.design	the non-negative x matrix used.

Author(s)

Mark W. Donoghoe <markdonoghoe@gmail.com>.

This function is based on code from Marschner and Gillett (2012) written by Alexandra Gillett.

plot.logbin.smooth *Default logbin.smooth Plotting*

Description

The main use is to take a fitted `logbin.smooth` object produced by `logbin.smooth` and plot the component smooth functions that make it up, for specified values of the other covariates.

Alternatively, plots the model diagnostics usually provided by `plot.lm`.

Usage

```
## S3 method for class 'logbin.smooth'
plot(x, type = c("response", "link", "diagnostics"), at = data.frame(),
     knotlines = TRUE, nobs = 1000, ...)
```

Arguments

<code>x</code>	a fitted <code>logbin.smooth</code> object as produced by <code>logbin.smooth</code> .
<code>type</code>	for "response" and "link", the type of prediction required. Note that, unlike <code>predict.logbin.smooth</code> , "terms" is not a valid option. For "diagnostics", <code>plot.lm</code> is called.
<code>at</code>	a data frame containing the values at which the prediction should be evaluated. The columns must contain the covariates in the model, and several rows may be provided (in which case, multiple lines are drawn on the same plot). Cannot be missing or NULL.
<code>knotlines</code>	logical; if vertical lines should be drawn on the plot to indicate the locations of the knots for B-spline terms.
<code>nobs</code>	the number of points which should be used to create the curve. These are placed evenly along the range of the observed covariate values from the original model.
<code>...</code>	other graphics parameters to pass on to plotting commands, in particular any arguments to <code>plot.lm</code> (e.g. which).

Details

For each smooth covariate in the model of `x`, `predict.logbin.smooth` is used to obtain predicted values for the range of that covariate, with the other covariates remaining fixed at their values given in `at`. Several rows may be provided in `at`, in which case, one curve is drawn for each, and they are coloured using `rainbow(nrow(at))`. If the model contains a single smooth covariate and no other covariates, `at` may be provided as an empty data frame, `data.frame()`.

Value

The function simply generates plots.

Note

If this function is too restrictive, it may be easier to use [predict.logbin.smooth](#) to get predictions for the dataset of your choice, and do the plotting manually.

```

predict.logbin	<i>Predict Method for logbin Fits</i>
----------------	---------------------------------------

Description

Obtains predictions from a fitted [logbin](#) object.

Usage

```
## S3 method for class 'logbin'
predict(object, newdata = NULL, type = c("link", "response", "terms"),
        terms = NULL, na.action = na.pass, checkminmax = TRUE, ...)
```

Arguments

object	a fitted object of class inheriting from "logbin".
newdata	optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
type	the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale. The value of this argument can be abbreviated.
terms	with type = "terms" by default all terms are returned. A character vector specifies which terms are to be returned.
na.action	function determining what should be done with missing values in newdata. The default is to predict NA.
checkminmax	logical indicating whether or not values of continuous covariates in newdata should be checked to ensure they lie within the covariate space associated with the fitted model. Otherwise predicted values could lie outside the parameter space.
...	further arguments passed to or from other methods.

Details

If newdata is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are treated is determined by the na.action argument of that fit. If na.action = na.omit, omitted cases will not appear in the residuals. If na.action = na.exclude they will appear, with residual value NA. See also [napredict](#).

Value

A vector or matrix of predictions. For type = "terms", this is a matrix with a column per term, and may have an attribute "constant".

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

```

predict.logbin.smooth *Predict Method for logbin.smooth Fits*

Description

Obtains predictions from a fitted `logbin.smooth` object.

Usage

```
## S3 method for class 'logbin.smooth'  
predict(object, newdata = NULL, type = c("link", "response", "terms"),  
        terms = NULL, na.action = na.pass, ...)
```

Arguments

object	a fitted object of class inheriting from "logbin.smooth".
newdata	optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
type	the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale. The value of this argument can be abbreviated.
terms	with type = "terms" by default all terms are returned. A character vector specifies which terms are to be returned.
na.action	function determining what should be done with missing values in newdata. The default is to predict NA.
...	further arguments passed to or from other methods.

Details

predict.logbin.smooth constructs the underlying basis functions for smooth variables in newdata and runs [predict.logbin](#) to obtain predictions. Note that if values of smooth covariates in newdata are outside the covariate space of object, an error will be returned.

If newdata is omitted, the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are treated is determined by the na.action argument of that fit. If na.action = na.omit, omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear, with residual value NA. See also [napredict](#).

Value

A vector or matrix of predictions. For type = "terms", this is a matrix with a column per term, and may have an attribute "constant".

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

```

summary.logbin

*Summarising logbin Model Fits***Description**

These functions are all [methods](#) for class `logbin` or `summary.logbin` objects.

Usage

```
## S3 method for class 'logbin'
summary(object, correlation = FALSE, ...)

## S3 method for class 'summary.logbin'
print(x, digits = max(3L, getOption("digits") - 3L),
      signif.stars = getOption("show.signif.stars"), ...)
```

Arguments

<code>object</code>	an object of class "logbin", usually from a call to logbin or logbin.smooth .
<code>x</code>	an object of class "summary.logbin", usually from a call to <code>summary.logbin</code> .
<code>correlation</code>	logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
<code>digits</code>	the number of significant digits to use when printing.
<code>signif.stars</code>	logical; if TRUE, 'significance stars' are printed for each coefficient.
<code>...</code>	further arguments passed to or from other methods.

Details

These perform the same function as [summary.glm](#) and [print.summary.glm](#), producing similar results for `logbin` models. `print.summary.logbin` additionally prints the small-sample corrected AIC (`aic.c`), and the number of EM iterations for the parameterisation corresponding to the MLE.

The dispersion used in calculating standard errors is fixed as 1.

Value

`summary.logbin` returns an object of class "summary.logbin", a list with components

<code>call</code>	the component from object.
<code>family</code>	the component from object.
<code>deviance</code>	the component from object.
<code>aic</code>	the component from object.
<code>aic.c</code>	the component from object.
<code>df.residual</code>	the component from object.
<code>null.deviance</code>	the component from object.

df.null	the component from object.
iter	the component from object.
deviance.resid	the deviance residuals: see residuals.glm .
coefficients	the matrix of coefficients, standard errors, z-values and p-values.
aliased	included for compatibility — always FALSE.
dispersion	the inferred/estimated dispersion.
df	included for compatibility — a 3-vector of the number of coefficients, the number of residual degrees of freedom, and the number of coefficients (again).
cov.unscaled	the unscaled (dispersion = 1) estimated covariance matrix of the estimated coefficients. NaN if object\$boundary == TRUE.
cov.scaled	ditto, scaled by dispersion.
correlation	if correlation is TRUE, the estimated correlations of the estimated coefficients. NaN if object\$boundary == TRUE.

Note

If object\$boundary == TRUE, the standard errors of the coefficients are not valid, and a matrix of NaNs is returned by [vcov.logbin](#). If the MLE is not on the boundary but the model contains parameters with monotonicity constraints, the standard errors do not take this into account and should be used with caution.

```

vcov.logbin	<i>Calculate Variance-Covariance Matrix for a Fitted logbin Model Object</i>
-------------	--

Description

Returns the variance-covariance matrix of the main parameters of a fitted logbin model object.

Usage

```
## S3 method for class 'logbin'
vcov(object, ...)
```

Arguments

object an object of class "logbin", usually from a call to [logbin](#) or [logbin.smooth](#).
... additional arguments for method functions.

Details

An equivalent method to [vcov](#), to use with [logbin](#) models.

Value

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the [coef](#) method.

Note

If `object$boundary == TRUE`, the standard errors of the coefficients are not valid, and a matrix of NaNs is returned.
